

STA240 Final Project

Anthony Zhao, Abby Li, William Yan

Scenario 1

Customer Arrival

Poisson process (rate = λ)

- T_k : Arrival time of the k th customer
- W_k : Time between the $k - 1$ th arrival and the k th arrival

$$W_k = T_k - T_{k-1}.$$

$$W_k \sim \text{Pois}(\lambda)$$

where $\lambda = 5$ customers per hour

Service Time

$$S_k \sim \text{Exp}(\lambda)$$

where $\lambda = 6$ customers per hour, so the average customer needs to wait $1/6$ hours = 10 minutes.

Arrival Times

```

library(tidyverse)
library(lubridate)

set.seed(121)

# simulating the arrival times of customers throughout the day

# Poisson process (lambda = 5)
# Tk= arrival time of the kth customer
# Wk= time between the k-1th customer arrival and the kth customer arrival where  $W_k \sim \text{Pois}(\lambda)$ 

# set parameter
lambdaA <- 5 # in units: customers per hour
opening_time <- hm("10:00")
closing_time <- hm("22:00")
hours <- hour(closing_time) - hour(opening_time) # operating hours: 10am to 10pm
total_time <- hours*60 # operating hours in minutes
lambdaA <- lambdaA/60 # customers per minute
# converting to minutes because our lambda is low, and we can get greater precision in a

n <- ceiling(lambdaA*total_time) # max number of customers the store can have throughout the

# generate W1,...,Wn (calculating the time between the arrival times of 2 customers)
W_sample <- rexp(n, rate= lambdaA)

# calculate T or the arrival times by summing together the Wi arrival times

T_sample <- numeric(n)

for(i in 1:n) {
  T_sample[i] <- sum(W_sample[1:i])
}

# all possible arrival times of customers throughout the day (X minutes after opening)
# however, the store is only open for 12 hours or 720 minutes so we must get rid of the values

arrival_times_s1 <- T_sample[T_sample <= total_time]

Arrival Times Analysis

In this simulation, the number of customers that will be arriving within the operating hours is 60, with the first customer arriving 15 minutes after opening and the last customer arriving 67 minutes before closing

Serving Times

```
# given the output from above, simulate the serving times of customers before they leave

# notice that service time is modeled by exp(6)
lambdaS <- 6 # customers per hour
lambdaS <- lambdaS/60 # customers per minute

# simulate customer's service time
# n= only simulating the service time for those where T_sample <= total_time
service_times_s1 <- rexp(length(arrival_times_s1), rate= lambdaS)

#these are the serving times for each arriving customer before they leave
service_times_s1
```

service_end <- numeric(length(arrival_times_s1))
current_end <- numeric(0) # service end time for current customer (i)

# iterate over each customer
for (i in 1:length(arrival_times_s1)) {

  # only includes observations where service time > arrival time => which means there is a wait
  # gets rid of observations where service < arrival time => 0 wait time
  if (length(current_end) > 0) {
    current_end <- current_end[current_end > arrival_times_s1[i]]
  }

  if (length(current_end) == 0) {
    # scenario 1: if there is no waiting time, service starts at the customer arrival
    service_start[i] <- arrival_times_s1[i]
  } else {
    # scenario 2: if there is a waiting time, service starts at the end of the previous customer's service
    previous_end <- service_end[i - 1]
    service_start[i] <- max(arrival_times_s1[i], previous_end)
  }

  # update the service end time for current customer by adding when service starts and how long it takes
  service_end[i] <- service_start[i] + service_times_s1[i]

  # add this service end time to current end services
  current_end <- c(current_end , service_end[i])

  # update waiting time
  waiting_times_s1[i] <- service_start[i] - arrival_times_s1[i]
}

scen1_sim_results <- data.frame(
  customer = 1:length(arrival_times_s1),
  arrival_time = arrival_times_s1,
  service_length = service_times_s1,
  service_start = service_start,

```

```

    service_end = service_end,
    waiting_time = waiting_times_s1,
    time_of_day = time_of_day
)

print(head(scen1_sim_results, 5)) # printing first 5 customers

```

	customer	arrival_time	service_length	service_start	service_end	waiting_time
1	1	15.48044	18.322653	15.48044	33.80309	0.00000

Serving and Waiting Times Analysis

```

# boxplot(service_times, horizontal= TRUE, main= "Service Times", xlab= "Minutes")

scen1_sim_results %>%
  ggplot(aes(x= service_length)) +
  geom_boxplot() +
  labs(
    x= "Minutes",
    title = "Service Times"
  ) +
  theme_minimal()

```

```
mean(service_times_s1)
```

```
[1] 10.65808
```

The average service time is 11 minutes, with the data skewed right, consistent with an exponential distribution. This indicates that service times tend to lower.

```
# boxplot(waiting_times, horizontal= TRUE, main= "Waiting Times", xlab= "Minutes")
```

```
mean(waiting_times_s1)
```

```
[1] 50.594
```

```
scen1_sim_results %>%
  ggplot(aes(x= waiting_time)) +
  geom_boxplot() +
  labs(
    x= "Minutes",
    title = "Waiting Times"
  ) +
  theme_minimal()
```

Waiting times tends to be slightly right-skewed and on average, the waiting time is 51 minutes.

```
#Label for 30 min interval
breaks <- seq(30, 720, by = 30)
labels <- sprintf("%02d:%02d", 10 + breaks %/% 60, breaks %% 60)

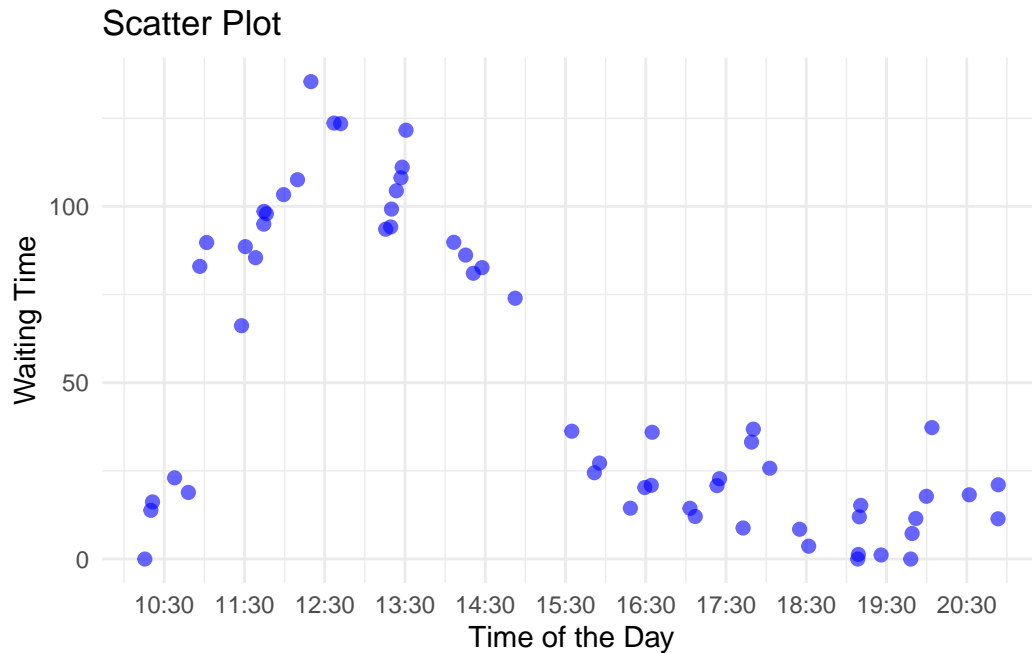

ggplot(scen1_sim_results, aes(x = time_of_day, y = waiting_times_s1)) +
  geom_point(color = "blue", size = 2, alpha = 0.6) +
  scale_x_discrete(
    breaks = breaks,
    labels = labels
  ) +
  labs(
    title = "Scatter Plot",
    x = "Time of the Day",
    y = "Waiting Time"
  ) +
  theme_minimal()
```

```
library(ggplot2)

# Custom breaks and labels for 30-minute intervals
breaks <- seq(30, 720, by = 60)
labels <- sprintf("%02d:%02d", 10 + breaks %/% 60, breaks %% 60)

# Scatter plot with x-axis as numeric time in minutes
ggplot(scen1_sim_results, aes(x = arrival_times_s1, y = waiting_times_s1)) +
  geom_point(color = "blue", size = 2, alpha = 0.6) +
  scale_x_continuous(
    breaks = breaks,
    labels = labels
  ) +
  labs(
    title = "Scatter Plot",
    x = "Time of the Day",
    y = "Waiting Time"
  ) +
  theme_minimal()
```

Scenario 2

Arrival and Service

Assumptions:

1. 5 dining tables and L chefs with operating hours 10am - 10pm
2. each table only seats one customer
3. service time modeled by an exponential distribution with rate $S = 3L$, so that the more chefs there are, the faster the service times become (**this is not very realistic**)

```
# first, we generate the arrival times similar in scenario 1
lambdaA <- 24 # per hour
opening_time <- hm("10:00")
closing_time <- hm("22:00")
hours <- hour(closing_time) - hour(opening_time)
total_time <- hours*60 # operating hours in minutes
lambdaA <- lambdaA/60 # per minute

n <- ceiling(lambdaA*total_time) # max number of customers
W_sample <- rexp(n, rate= lambdaA)
```

```

T_sample <- numeric(n)

for(i in 1:n) {
  T_sample[i] <- sum(W_sample[1:i])
}

arrival_times <- T_sample[T_sample <= total_time]

# next, we generate the service times similar to scenario 1
# make a function to do this
calc_service_times <- function(arrivals, chefs) {
  # Ensure rate is per unit time
  minute_rate = (3*chefs) / 60
  services = rexp(length(arrivals), rate = minute_rate)
  return(services) # in minutes
}
# if we only have one chef
service_times <- calc_service_times(arrivals = arrival_times, chefs = 2)

```

Waiting Times

To model waiting times, we iterate through the day minute by minute.

```

tables <- 5
arrival_times_temp <- arrival_times

# number of people in line each minute
queue_size_history <- numeric(total_time)

# number of tables occupied each minute
occupied_tables_history <- rep(0, total_time)

# timer to track remaining waiting time for each table in the restaurant
# each element is one table in the restaurant
# -1 means empty
# otherwise, number of remaining service minutes
tables_timer <- rep(-1, tables)

# the amount of minutes each customer of that day waited
waiting_times <- numeric(0)

```

```

# the arrival_times indices of the people currently in line
# in order to know how long their eventual service time will be
queue <- numeric(0)

# an internal counter separate from the time
customers_entered <- 0
for (i in 1:total_time) {
  occupied_tables_history[i+1] = occupied_tables_history[i]

  # update the waiting timer for all occupied tables
  tables_timer[tables_timer > 0] <- tables_timer[tables_timer > 0] - 1
  # update the number of available tables in the next minute
  # based on the number of tables who have finished timers
  occupied_tables_history[i+1] = occupied_tables_history[i+1] - sum(tables_timer == 0)
  # mark the finished tables as available tables for the next minute
  tables_timer[tables_timer == 0] <- tables_timer[tables_timer == 0] + 1

  # has the next customer arrived?
  if(length(arrival_times_temp) > 0){
    if(arrival_times_temp[1] < i) {
      # if so, add them to the back of the queue
      queue = c(queue, as.integer(customers_entered+1)) # add 1 for 1-indexing
      # remove the 1st element of arrival_times
      arrival_times_temp = arrival_times_temp[-1]
      # start the waiting timer for this customer by appending 0
      waiting_times = c(waiting_times, 0)

      customers_entered = customers_entered + 1
    }
  }

  # are any tables currently open and there is a person in line?
  if(occupied_tables_history[i+1] < tables & length(queue) > 0) {
    # if so, then seat the first person in line
    # at the first available table
    for (j in 1:tables) {
      if(tables_timer[j] == -1) {
        # queue[1] has the customer index of the first person in line
        tables_timer[j] = round(service_times[queue[1]])
        break
      }
    }
  }

  # the next minute there will be one more occupied table

```

```

    occupied_tables_history[i+1] = occupied_tables_history[i+1] + 1
    # remove the first person in the queue
    queue = queue[-1]
  }
  # update the waiting time for each person in the queue
  for (customer_index in queue) {

Restaurant Profits

Assumptions:

1. each customer spends \$50 per meal (customers who are still in the queue when the restaurant closes won't pay)
2. each chef earns a wage of \$40 per hour (paid for the entire duration of the restaurant's operating hours)

```
# assumption of five tables and 3 chefs

# setting number of chefs to a certain number
# chefs <- 3
# meal <- 50 #50 dollars per meal
# wage <- 12*40 #40 dollars per hour for 12 hrs of work
# revenue <- total_customers * meal
# costs <- wage*chefs
# profit <- revenue - costs
# profit

# only including customers who are waiting for less than 30 mins because will leave the line
```

```

filtered_customers <- which(waiting_times < 30)
total_customers <- length(filtered_customers)
total_customers

```

```
[1] 270
```

```

meal <- 50 #50 dollars per meal
wage <- 12*40 #40 dollars per hour for 12 hrs of work

profit_table <- data.frame(
  Chefs = integer(),
  Revenue = numeric(),
  Costs = numeric(),
  Profit = numeric()
)

# if people get mad, the meal will only be 25 because they are mad

for (chefs in 1:10) {

  revenue <- total_customers * meal

  # Calculate costs (wage per chef * number of chefs)
  costs <- wage * chefs

  # Calculate profit
  profit <- revenue - costs

  profit_table <- rbind(profit_table, data.frame(Chefs = chefs, Revenue = revenue, Costs = costs, Profit = profit))
}

print(profit_table)

```

	Chefs	Revenue	Costs	Profit

10	10	13500	4800	8700

Maximizing Profits

Should we run this simulation multiple times to create a PDF of the total daily profits? How many chefs should we hire?

Down-time of Restaurant

How does the occupancy of the restaurant vary throughout the day? Does that inform any of our recommendations?
